

# Type inference

DENIS MIGINSKY

# Questions of the day

- ▶ Why do we need types in programming languages (PL)?
- ▶ What is a type in PL?
- ▶ Can we have PLs without types?
- ▶ What are the differences and similarities between types in PL and types in  $\lambda$ -calculus?

# Type's purposes

1. How does a type relate to other types? What is the structures and representation of a type? How to construct instances of a type and extract their parts?  
Ex:  $\text{Complex} ::= \text{Float} \times \text{Float}$
2. How do instances of a type behave?  
Ex:  $\text{sum} : \text{Complex} \rightarrow \text{Complex} \rightarrow \text{Complex}$
3. Check the overall correctness of the program (syntactic level only!) without running it  
Ex: `sum 2 "word"` – justify that this is incorrect program!

# Static and dynamic typing

In languages with **static typing** types are used for checking/inference in compile time.

**Pros:** a compiler does a lot of work to verify the correctness of a program.

**Cons:** static typing usually limits the capabilities of a language (consider the array with arbitrary types of elements) and extend the amount of “redundant” code. The problems are less significant with more advanced type system.

In languages with **dynamic typing** types are used only in runtime to determine possible behavior.

**Pros:** no limitations from a type system, a compiler is fast

**Cons:** a lack of static type verification requires other techniques to manage quality. Dynamic type checking is usually much simpler than dynamic, but it also takes time. Dynamic languages are significantly slower.

Don't mess with strong and weak typing. Both of these are strong!

# Type: $\lambda$ vs programming languages

$\lambda$ -calculus	C	Haskell	Java	$\lambda$ in Clojure syntax
$x: \text{Int} \vdash x$	<code>int x; x;</code>			<code>{x :Int} x</code>
$\text{inc}: \text{Int} \rightarrow \text{Int} \vdash \text{inc } x$		<code>inc :: Int -&gt; Int</code> <code>inc x</code>		<code>{inc (-&gt; :Int :Int)} (inc x)</code>
$x: \text{List Int} \vdash \text{head } x$			<code>List&lt;Integer&gt; x;</code> <code>x.get(0);</code>	<code>{x (:List :Int)} (head x)</code>
$\vdash \lambda x.x$		<code>\x -&gt; x</code>	<code>&lt;T&gt; T f (T x) {return x;}</code> <code>x -&gt; x</code>	<code>{ } (lambda x x)</code>
$\vdash (\lambda x.x) 10$		<code>(\x -&gt; x) 10</code>		<code>{ } ((lambda x x) 10)</code>
$\text{add}: \text{Int} \rightarrow \text{Int} \rightarrow \text{Int} \vdash (\lambda xy.\text{add } x \ y)$	<code>int add (int x, int y){</code> ... <code>}</code> <code>//what next?</code>			<code>{add (-&gt; :Int</code> <code>(-&gt; :Int :Int)) }</code> <code>(lambda x</code> <code>(lambda y (add x y)))</code>
$\text{add} : \text{Int} \times \text{Int} \rightarrow \text{Int}$	<code>int add (int x, int y){</code> ... <code>}</code>	<code>add :: (Int, Int)</code> <code>-&gt;Int</code>		<code>{add (-&gt; (cross :Int :Int</code> <code>:Int)) }</code>
$\text{Str} \times \text{Int} \times \text{Int}$	<code>struct {</code> <code>char* name;</code> <code>int x, y;}</code>	<code>(String, Int, Int)</code>		<code>(cross :Str :Int :Int)</code>

Fill the gaps

# Type inference problem

**Type inference (reconstruction) problem:** for the given term and the context ( $\Gamma$ ) for each subterm (including the term itself) the following should be done:

- ▶ If a subterm has known type: check, if it is correct (**type checking**)
- ▶ If a subterm has no type: infer this type or prove that it is impossible (**type inference**)

## Inference:

$y: \text{Str} \vdash (\lambda x: ? . y) : ?$   
 $x: \text{Int}, +: \text{Int} \rightarrow \text{Int} \rightarrow \text{Int} \vdash (\lambda y: ? . (x + y): ?) : ?$   
 $\vdash ((\lambda x: ? . x): ? \ 10) : ?$

## Checking:

$+: \text{Int} \rightarrow \text{Int} \rightarrow \text{Int} \vdash (\lambda x: \text{Int} . \lambda y: \text{Str} . x + y): \text{Int} \rightarrow \text{Int} \rightarrow \text{Str}$

# Simply typed $\lambda$ -calculus

$$\frac{x: \alpha \in \Gamma}{\Gamma \vdash x : \alpha} [Var]$$

When a **variable** is met, its type should be taken from the current **lexical scope**

$$\frac{\alpha = \text{typeOfConst}(c)}{\vdash c : \alpha} [Const]$$

When a **constant** is met, its type should be known from the language syntax

$$\frac{\Gamma \vdash f : \alpha \rightarrow \beta \quad \Gamma \vdash x : \alpha}{\Gamma \vdash f \ x : \beta} [App]$$

When an **application** is met:

1. Infer the type of the **function** to be in form  $\alpha \rightarrow \beta$  (or fail otherwise)
2. Infer the type of the **actual argument**, it must be  $\alpha$  (or fail otherwise)

Now it can be deduced that the type of the whole **application** is  $\beta$

$$\frac{\Gamma, x : \alpha \vdash y : \beta}{\Gamma \vdash \lambda x. y : \alpha \rightarrow \beta} [Abs]$$

When an **abstraction (function definition)** is met:

1. Make sure that type  $\alpha$  of the **formal argument** is provided
2. Infer the **body** type  $\beta$  in the scope  $\Gamma$  enriched with  $x:\alpha$

Now it can be deduced that the type of the **function** is  $\alpha \rightarrow \beta$

This is type checking mostly, not inference

# Example: inference algorithm

$$\frac{x: \alpha \in \Gamma}{\Gamma \vdash x : \alpha} \text{ [Var]}$$

$$\frac{\alpha = \text{typeOfConst}(c)}{\vdash c : \alpha} \text{ [Const]}$$

$$\frac{\Gamma \vdash f : \alpha \rightarrow \beta \quad \Gamma \vdash x : \alpha}{\Gamma \vdash f x : \beta} \text{ [App]}$$

$$\frac{\Gamma, x : \alpha \vdash y : \beta}{\Gamma \vdash \lambda x. y : \alpha \rightarrow \beta} \text{ [Abs]}$$

## Problem:

$\Gamma = \{\text{inc} : \text{Int} \rightarrow \text{Int}\}$   
 $\Gamma \vdash (\lambda x : \text{Int} . \text{inc } x : ?) : ?$

## Solution:

1.  $\text{infer } (\Gamma, (\lambda x : \text{Int} . \text{inc } x : ?))$  **[Abs]**  $\text{Int} \rightarrow \text{infer } (\{\Gamma, x : \text{Int}\}, \text{inc } x)$
2.  $\text{infer } (\{\Gamma, y : \text{Int}\}, \text{inc } x)$  **[App]**  $\text{check}(\text{typeOf}(\text{inc}) = * \rightarrow *)$ ,  
 $\text{check}(\text{infer}(\{\Gamma, x : \text{Int}\}, x) = \text{Int})$ ,  
 $\text{Int}$
3.  $\text{infer}(\{\Gamma, x : \text{Int}\}, x)$  **[Var]**  $\text{Int}$
4. in step 2: check is OK,  $\text{Int}$
5. in step 1:  $\text{Int} \rightarrow \text{Int}$

## Problem:

$((\lambda x. x) 10)$

## Solution:

???

# Notes on practical application

- ▶ The type systems itself is very simple
- ▶ This is pretty close to C type system

## Cons:

- ▶ There are no composite types like tuples, records (this is trivial extension)
- ▶ There are no named function definitions (not so hard)
- ▶ There is no recursion (a little bit harder)
- ▶ **Lack of inference possibilities.** That is why C (and many other static typing languages) requires the explicit typing of almost everything (unlike Haskell, for instance). **This is more difficult.**

# Tuple extension

$$\frac{\Gamma \vdash x_1 : \alpha_1 \dots \Gamma \vdash x_n : \alpha_n}{\Gamma \vdash (x_1 \dots x_n) : \alpha_1 \times \dots \times \alpha_n} [Tuple]$$

A **record** (or a structure in C) is pretty similar, only syntax is a little bit different

# Let extension

**Syntax:**  $let\ x = y\ in\ z$

**Semantics:** substitute  $x$  with  $y$  inside  $z$ :  $\frac{let\ x = y\ in\ z}{z[x/y]}$

**Types:**

$$\frac{\Gamma \vdash y : \alpha \quad \Gamma, x:\alpha \vdash z : \beta}{\Gamma \vdash let\ x = y\ in\ z : \beta} [Let]$$

When a **let clause** is met:

1. Infer the type of the **substitution** ( $y$ )  $\alpha$ , **variable** ( $x$ ) is of the same type
2. Infer the type of the **body** ( $z$ )  $\beta$  with outer **scope** ( $\Gamma$ ) enriched with  $x: \alpha$

Unlike the evaluation, there is no need to apply the substitution to infer the type of **body**.

# Letrec extension

## Syntax:

*letrec* **x** = **y** in **z**

## Semantics (informally):

evaluate **y** with assumption that **x** is already defined and available (recursively). Next, substitute **x** inside **z** with the evaluation result of **y**

## Types:

$$\frac{\Gamma, x:\alpha \vdash y:\alpha \quad \Gamma, x:\alpha \vdash z:\beta}{\Gamma \vdash \text{let } x = y \text{ in } z : \beta} \text{ [LetRec]}$$

When the **letrec clause** is met:

1. Infer the type of the **substitution** (**y**) with outer **scope** ( $\Gamma$ ) enriched with **x**:  $\alpha$ . The inferred type must be  $\alpha$ .
2. Infer the type of the **body** (**z**)  $\beta$  with outer **scope** ( $\Gamma$ ) enriched with **x**:  $\alpha$ . Unlike the evaluation, there is no need to apply the substitution to infer the type of **body**.

Unlike **let**, in **letrec** the type for **x** must be explicitly provided in simple calculus

# Monomorphic and polymorphic types

$\vdash 42: \text{Int}$  monomorphic type (monotype)  
 $\text{inc}: \text{Int} \rightarrow \text{Int} \vdash \text{inc}: \text{Int} \rightarrow \text{Int}$  monotype  
 $\text{inc}: \text{Int} \rightarrow \text{Int} \vdash \text{inc } 42: \text{Int}$  monotype

$\vdash \lambda x.x : ???$  cannot be typed in our current calculus

**But**, we can reason that the last term has:

1. some functional type, and
2. the argument and the result are of the same type.

**So:**

$\vdash \lambda x.x : \omega \rightarrow \omega$

Where  $\omega$  is a kind of variable. Because all the possible binding of  $\omega$  are types, it is called **type variable**.

$\omega \rightarrow \omega$  or, more formally,  $\forall \omega. \omega \rightarrow \omega$  is a **polymorphic type (polytype)**, i.e. type with at least one unresolved type variable.

# Examples of useful polytypes

list:  $\text{List } \alpha$

first:  $\text{List } \alpha \rightarrow \alpha$

size: ???

map:  $\text{List } \alpha \rightarrow (\alpha \rightarrow \beta) \rightarrow \text{List } \beta$

filter: ???

genericMap:  $\zeta \alpha \rightarrow (\alpha \rightarrow \beta) \rightarrow \zeta \beta$

reduce/fold:  $\text{List } \alpha \rightarrow \beta \rightarrow (\alpha \rightarrow \beta \rightarrow \beta) \rightarrow \beta$

If-then-else: ???

# Generalization and instantiation

$\beta = \text{inst}(\alpha)$  means that there is a substitution  $\mathbf{S}$  that  $\beta = \alpha\mathbf{S}$

$\alpha$  is **more general** type and  $\beta$  is **more specific** type in this case

## Examples:

$\text{Int} = \text{inst}(\alpha), \mathbf{S} = [\alpha/\text{Int}]$

$\text{Int} \rightarrow \text{Int} = \text{inst}(\alpha \rightarrow \alpha), \mathbf{S} = [\alpha/\text{Int}]$

$\alpha \rightarrow \text{Int} \rightarrow \text{Int} = \text{inst}(\alpha \rightarrow \beta), \mathbf{S} = [\beta/\text{Int} \rightarrow \text{Int}]$

$\alpha \rightarrow \alpha = \text{inst}(\alpha \rightarrow \beta), \mathbf{S} = [\beta/\alpha]$

- ▶  $\alpha = \text{inst}(\alpha)$  for any  $\alpha$
- ▶ A **monotype** has no more specific types besides itself.
- ▶ A **polytype** of kind  $\alpha$  (just a single type variable) is the most general polytype

# Polytypes in type inference

**Problem:**  $\vdash ((\lambda x:?.x:?) :? 10) : ?$

**Solution:**

- |  |              |  |
|--|--------------|--|
| 1. <code>infer</code> ( <code>{}</code> , <code>((<math>\lambda x:?.x:?</math>) :? 10))</code> | <b>[App]</b> | <code>infer</code> ( <code>{}</code> , <code><math>\lambda x:?.x:?</math></code> ) = $\alpha \rightarrow \beta$ ,<br><code>10:Int</code> ,<br><code>unify</code> ( $\alpha$ , <code>Int</code> ) = [ $\alpha$ / <code>Int</code> ] |
| 2. <code>infer</code> ( <code>{}</code> , <code>(<math>\lambda x:?.x:?</math>) :?</code> )     | <b>[Abs]</b> | <code>infer</code> ( <code>{x: Int}</code> , <code>x/*body*/</code> ) = $\beta$ ,<br><code>unify</code> ( <code>Int</code> , $\beta$ ) = [ $\beta$ / <code>Int</code> ]  |

`unify`( $\alpha$ ,  $\beta$ ) finds the **most general unification** for  $\alpha$  and  $\beta$  (with Robinson algorithm or any other) or fails.

# Hindley-Milner type system: basic rules

$$\frac{\alpha = \text{typeOfConst}(c)}{\vdash c : \alpha} \quad [\text{Const}]$$

$$\frac{x : \alpha \in \Gamma}{\Gamma \vdash x : \alpha} \quad [\text{Var}]$$

$$\frac{\Gamma \vdash x_1 : \alpha_1 \dots \Gamma \vdash x_n : \alpha_n}{\Gamma \vdash (x_1 \dots x_n) : \alpha_1 \times \dots \times \alpha_n} \quad [\text{Tuple}]$$

$$\frac{x \notin \text{free}(\Gamma) \quad \omega = \text{newvar}}{\Gamma \vdash x : \omega} \quad [\text{AVar2}]$$

When a **variable** is met that is not defined in the **scope**, assume that its type is of some **type variable**, not used before ( $\omega = \text{newvar}$ ).

When an **abstraction (function definition)** is met:

1. Get new type variable for the formal argument
2. Infer the **body** type  $\beta$  in the scope  $\Gamma$  enriched with  $x : \omega$

Now it can be deduced that the type of the **function** is  $\omega \rightarrow \beta$

$$\frac{\omega = \text{newvar} \quad \Gamma, x : \omega \vdash y : \beta}{\Gamma \vdash \lambda x. y : \omega \rightarrow \beta} \quad [\text{AAbs}]$$

When an **application** is met:

1. Infer the type of the **function** to be in form  $\alpha \rightarrow \beta$  (or fail)
2. Infer the type  $\alpha'$  of the **actual argument**, and perform **unification** with  $\alpha$

Now it can be deduced that the type of the whole **application** is  $\beta$

$$\frac{\Gamma \vdash f : \alpha \rightarrow \beta \quad \Gamma \vdash x : \alpha' \quad \text{unify}(\alpha, \alpha')}{\Gamma \vdash f \ x : \beta} \quad [\text{AApp}]$$

# Let polymorphism

## Problems:

$\vdash ((\lambda f x y. (f x, f y)) (\lambda x. x) : ? \ 10 \text{ "abc"}) : ?$

$\vdash (\text{let } f = (\lambda x. x) : ? \text{ in } (f \ 10, f \text{ "abc"})) : ?$

**f** will have different monotypes in different situations.  
So the unification will fail.

**Extension:** don't ask about **f**'s type

$\vdash (\text{let } f = (\lambda x. x) \text{ in } (f \ 10, f \text{ "abc"})) : ?$

And replace the rule with the following:

$$\frac{\Gamma \vdash [x/y] z : \beta}{\Gamma \vdash \text{let } x = y \text{ in } z : \beta} [ALet]$$

For a **let clause**:

1. Apply syntactic substitution  $[x/y] z$
2. Infer the type of  $z$  after the substitution. Type for  $y$  will be inferred separately for each occurrence inside  $z$

```
//Java: the same as polymorphic let
public class SomeClass{
    public static <X> X f(X x){
        return x;
    }
    public static void main(){
        System.out.println(
            new Tuple2<Integer, String>(
                f(10), f("abc")));
    }
}
```

# Letrec with polymorphism

*letrec* **x** = **y** in **z**

A type for this clause with polymorphic extension cannot be inferred by simple substitution **z** [**x/y**] because **y** can also contain **x** for recursion purposes.

**Strategy:** evaluate **letrec** as there is separate **letrec** definition for each occurrence of **x** inside **z**

For a **letrec clause**:

1. Find all the occurrences of **x** in **z**
2. For each occurrence **i**:
  - a) Generate new variable **x<sub>i</sub>**  
to replace **x**, type variable **ω<sub>i</sub>** for it and apply the substitution **y<sub>i</sub> = y[x/x<sub>i</sub>]**
  - b) Infer the type of **y<sub>i</sub>** in the scope enriched with **x<sub>i</sub> : ω<sub>i</sub>** and unify it with **ω<sub>i</sub>**.
  - c) Substitute this occurrence of **x** in **z** with **x<sub>i</sub>**
3. Now infer the type of **z** with all the substitutions in the scope enriched with **∀i. x<sub>i</sub> : ω<sub>i</sub>**

$$\frac{\begin{array}{l} \forall i. \omega_i = \text{newvar} \quad \forall i. x_i = \text{newvar} \quad \forall i. y_i = y[x/x_i] \\ \forall i \Gamma, x_i : \omega_i \vdash y_i : \alpha_i \quad \forall i. \text{unify}(y(\omega_i, \alpha_i)) \\ \Gamma, \forall i. x_i : \omega_i \vdash z[x / x_1 \dots x_n] : \beta \end{array}}{\Gamma \vdash \text{letrec } x = y \text{ in } z : \beta} \quad [\text{ALetRec}]$$

# Hindley-Milner type system: inference algorithm

With given scopes of term variables  $\Gamma$  and empty scope of substitutions  $\Omega$  for type variables:

1. Take the top-most syntactic structure
  2. Find appropriate rule and apply it (there will be only one for each case)
  3. All the unifications update  $\Omega$
- Some of the rules are recursive, i.e. they “ask” to infer types of sub-clauses of a given clause.
  - Scopes of **term variables** are different for different nodes of syntax tree.  
In different branches there could be different term variables with the same name.
  - Scope of **type variables**  $\Omega$  is global.

# Extended Hindley-Milner type system: rules for algorithm

$$\frac{x: \alpha \in \Gamma}{\Gamma \vdash x : \alpha} [Var]$$

$$\frac{\omega = \text{newvar} \quad \Gamma, x : \omega \vdash y : \beta}{\Gamma \vdash \lambda x. y : \omega \rightarrow \beta} [AAbs]$$

$$\frac{x \notin \text{free}(\Gamma) \quad \omega = \text{newvar}}{\Gamma \vdash x : \omega} [AVar2]$$

$$\frac{\Gamma \vdash f : \alpha \rightarrow \beta \quad \Gamma \vdash x : \alpha' \quad \text{unify}(\alpha, \alpha')}{\Gamma \vdash f x : \beta} [AApp]$$

$$\frac{\alpha = \text{typeOfConst}(c)}{\vdash c : \alpha} [Const]$$

$$\frac{\begin{array}{l} \forall i. \omega_i = \text{newvar} \quad \forall i. x_i = \text{newvar} \quad \forall i. y_i = y[x/x_i] \\ \forall i. \Gamma, x_i : \omega_i \vdash y_i : \alpha_i \quad \forall i. \text{unify}(\omega_i, \alpha_i) \\ \Gamma, \forall i. x_i : \omega_i \vdash z[x / x_1 \dots x_n] : \beta \end{array}}{\Gamma \vdash \text{letrec } x = y \text{ in } z : \beta} [ALetRec]$$

$$\frac{\Gamma \vdash x_1 : \alpha_1 \dots \Gamma \vdash x_n : \alpha_n}{\Gamma \vdash (x_1 \dots x_n) : \alpha_1 \times \dots \times \alpha_n} [Tuple]$$
